

WSU EXTENSION FORESTRY

Western Washington Stand Dynamics

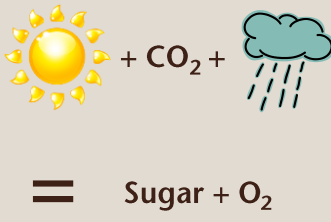

Presented By:
 Kevin W. Zobrist
 Associate Professor
 Washington State University Extension

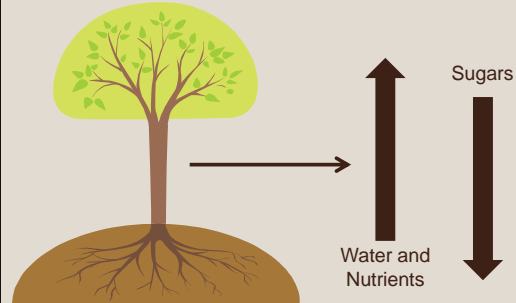

A stand is an area of similar forest vegetation.

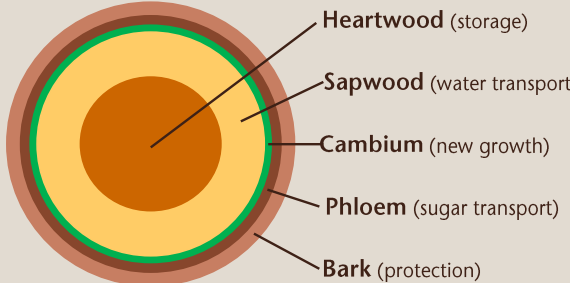

Forests are solar-powered.

Tree stems are critical transport pathways between the crown and the roots.

Different parts of the tree stem have different functions.

K.W. Zobrist, WSU Extension

The forest development cycle begins and ends with a stand-replacing disturbance.

Stand initiation is the first stage of forest development.

Succession is the change in the mix of tree species present in a stand over time.

K.W. Zobrist, WSU Extension

Forest communities vary in space and time based on competitive advantage.

Succession tends to begin with fast-growing, shade-intolerant pioneer species.

Stem exclusion is the dark, dense second stage of development.

There is a limiting relationship between stand density and tree size.

During this competitive process, trees differentiate into different crown classes.

In understory reinitiation, space begins to open up for understory trees and shrubs.

Over time, shade-tolerant species fill in gaps.

Continued development without disturbance results in the complex old growth stage.

The formation of gaps is an important part of late-successional development.

Here are a few summary points.

1. Forests are dynamic.
2. Disturbance is not necessarily a bad thing.
3. Density management is important.
4. Keep diversity in mind.
